- Thanks to the NSERC and the CFI for funding my research.
- Thanks to Prof. Xuekui Zhang for inviting me to this session.

# Outline

- 1 Introduction
- 2 Review of Existing Model Checking Methods for Censored Regression
- 3 Normalized Randomized Survival Probabilities (Z-residuals)
- 4 A Simulation Study
- 5 A Real Data Example
- 6 Conclusions and Future Work

# Section 1

## Introduction

- Residual diagnostics is a standard tool for checking the overall goodness-of-fit (GOF) of normal regression models, graphically and numerically. It can also help identify the nature of the model mis-specification, eg, non-linear covariate effect.
- However, similar residual diagnostic tools are not completely available for censored regression.
- It is desired to have a tool like residual diagnostics for censored regression. In this paper, we propose to diagnose censored regression with a new residual called normalized randomized survival probabilities (NRSP). In particular, we show its effectiveness in detecting non-linear covariate effect.

## Section 2

# Review of Existing Model Checking Methods for Censored Regression

# When there is no censoring

- Suppose the survival function of  $T_i^*$  based on a model is defined as  $S_i(t_i^*) = P(T_i^* > t_i^*)$ , where the subscript  $i$  indicates that the probability depends covariate  $x_i$  for the  $i$ th individual.
- The survival probabilities  $S_i(T_i^*)$  are uniformly distributed when  $S_i(\cdot)$  is the true survival function of  $T_i^*$ .  $S_i(T_i^*)$  can be transformed to follow any desired distribution:
  - Cox-Snell (CS) residual is defined as

$$r_i^c(T_i^*) = -\log(S_i(T_i^*)),$$

where  $-\log(\cdot)$  is the inverse survival function of  $\exp(1)$ . Therefore, CS residuals are exponentially distributed under the true model.

- One can also define normally-distributed residuals:

$$r_i^n(T_i^*) = \Phi^{-1}(S_i(T_i^*)),$$

which we call by **normalized SPs**. Then we can apply a variety of residual diagnostic methods for normal regression to diagnose  $S_i(\cdot)$ .

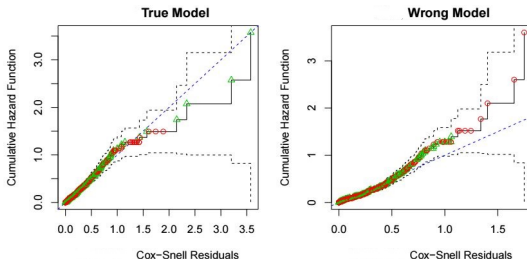

# When censoring occurs

- When  $T_i^*$  is right-censored, we only observe  $(T_i, d_i)$ , where  $T_i = \min(T_i^*, C_i)$ ,  $d_i = I(T_i^* < C_i)$ .
- Since  $T_i < T_i^*$ ,  $S_i(T_i) > S_i(T_i^*)$ . We call  $S(T_i)$  **unmodified survival probabilities**.
- $S_i(T_i)$  is not uniformly distributed:
  - $S_i(T_i)$  is a left-censored observation of the uniform distribution.
  - The **unmodified CS residuals**,  $r_i^c(T_i) = -\log(S_i(T_i))$  is a right-censored observation from  $\exp(1)$  under the true model.
  - The **normalized unmodified SPs (NUSP)**,  $r_i^n(T_i)$  is a left-censored observation from  $N(0,1)$  under the true model.

# Overall GOF Checking for Censored Data

- The most widely used diagnostic tool is to apply KM methods to  $\{(r_i^c(T_i), d_i) | i = 1, \dots, n\}$  to get an estimate of the CHF of CS residuals. Under the true model, the CHF of CS residuals is expected to be close to the 45° straight line.

- Shapiro-Francia normality test has also been extended to censored data (available in R package `EnvStats`). We can apply this method to NUSP ( $\Phi^{-1}(S_i(T_i))$ ), which we call **NUSP-CSF** method.

# Overall GOF Checking for Censored Data (contd.)

- Checking the distribution of residuals is only the first-line model diagnostics. The GOF test results typically cannot reveal the nature of model mis-specification, for example non-linear effects, lack of independence, and heterogeneous variance.
- Therefore, it may not help improve our models.

## Other Residuals for Censored Observations

- A commonly used method is to shrink the USPs of the censored failure times:

$$S'_i(T_i, d_i, \eta) = \eta S_i(T_i), \quad \text{if } T_i \text{ is censored, i.e., } d_i = 0, \quad (1)$$

where  $\eta \in (0, 1)$ . Different choices of  $\eta$  exist based on different arguments, eg,  $1/2, 1/e$ , corresponding to adding  $\log(2)$  or  $1$  to CS residuals. There are also other residuals like martigale and deviance residuals. The residuals for censored  $T_i$  are modified similarly with a **non-random** scheme.

- **Problem:** All these residuals lack a known reference distribution under censoring; this creates the obstacle in applying a variety of residual diagnostics tools, especially in quantifying the degree of model violation.

## Section 3

# Normalized Randomized Survival Probabilities (Z-residuals)

- The randomized survival probability (**RSP**) for  $T_i$  is defined as:

$$S_i^R(T_i, d_i, U_i) = \begin{cases} S_i(T_i), & \text{if } T_i \text{ is uncensored, i.e., } d_i = 1, \\ U_i S_i(T_i), & \text{if } T_i \text{ is censored, i.e., } d_i = 0, \end{cases} \quad (2)$$

where  $U_i$  is a uniform random number on  $(0, 1)$ .

# Illustration of the Uniformity of RSP

(a) RSPs, True Model

(b) Hist of RSPs, True Model

(c) RSPs, Wrong Model

(d) Hist of RSPs, Wrong Model

Figure 1: Illustration of the uniformity of RSPs.

# Normalized RSP Residuals (Z-residuals)

- We can prove that the randomized SP is uniformly distributed on  $(0, 1)$  given  $x_i$  under the true model.
- We can transform them into residuals with any desired distribution. We prefer to transforming them with the normal quantile:

$$r_i^{\text{NRSP}}(T_i, d_i, U_i) = \Phi^{-1}(S_i^R(T_i, d_i, U_i)). \quad (3)$$

- We call the residuals in (3) by normalized randomized SP (**NRSP**) residuals. Now we feel that Z-residual is a better name.

## Section 4

# A Simulation Study

- The response variable is simulated from a Weibull AFT regression model with a non-linear link function:  $\log(T_i^*) = 2 + 5 \sin(2x_i) + \epsilon_i$ . The covariate  $x_i$  was generated uniformly on  $(0, 3\pi/2)$ . The shape parameter of the Weibull distribution was set as 1.8. The censoring times  $C_i$  were generated from  $\exp(\theta)$  with  $\theta$  varied for obtaining different censoring rates.
- We considered fitting a Weibull AFT model assuming  $\log(T_i^*) = \beta_0 + \beta_1 x_i + \epsilon_i$  as a wrong model, and fitting a Weibull AFT model assuming  $\log(T_i^*) = \beta_0 + \beta_1 \sin(2x_i) + \epsilon_i$  as the true model.

# Graphical Model Checking

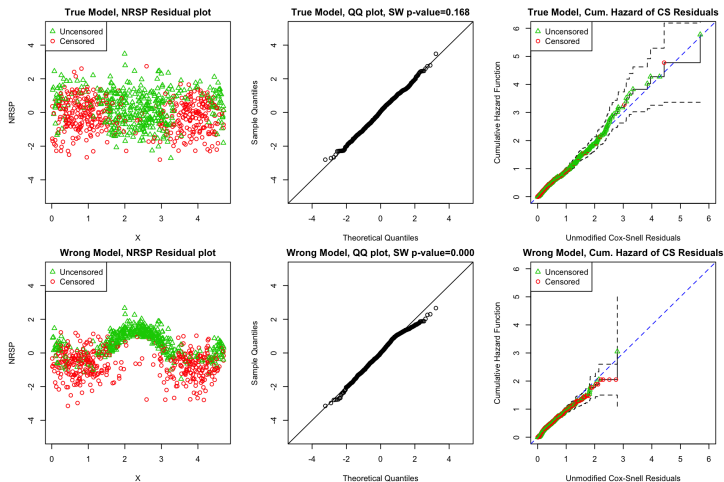

Figure 2: Performance of the NRSP residuals as a graphical tool for detecting non-linear effect in covariate. The dataset has a sample size  $n = 800$  and a censoring rate  $c \approx 50\%$ .

# Comparison of Statistical Tests

**Table 1:** Comparison of the percentages of model rejections of various statistical tests. A model is rejected when the test p-value is smaller than 0.05.

Notes:

- NRSP-AOV: a non-linearity test based on NRSP residuals.
- NUSP-CSF: an extended SF normality test based on NUSP (censored data).

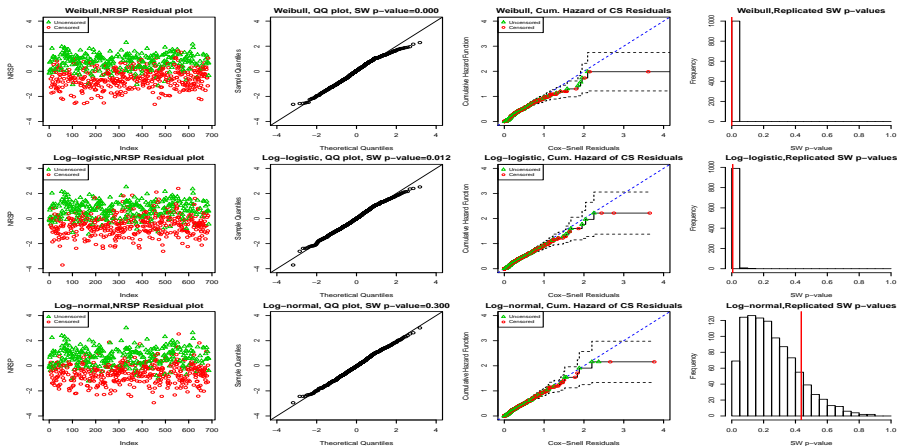

## Section 5

### A Real Data Example

# A Breast Cancer Recurrent-free Dataset

- Source:  
Schumacher M, Bastert G, Bojar H, et al. Randomized 2 x 2 Trial Evaluating Hormonal Treatment and the Duration of Chemotherapy in Node-Positive Breast Cancer Patients. German Breast Cancer Study Group.. Journal of Clinical Oncology 1994; 12(10): 2086-2093. doi: 10.1200/JCO.1994.12.10.2086
- The sample size is 686. The censoring rate is 56.5%.
- The response variable of interest is the recurrence-free time, which is the time from entry to the study until a recurrence of cancer or death.
- We consider the following covariates: the tamoxifen treatment indicator, patient age, menopausal status, size and grade of the tumour, number of positive lymph nodes, progesterone and estrogen receptor status.

# Graphical Checking and NRSP-based GOF Tests

**Figure 3:** NRSP residuals of the Weibull, log-logistic, and log-normal AFT models fitted to the breast cancer patients dataset. The last column presents the histograms of 1000 replicated NRSP-SW p-values of each model. The vertical red lines indicate  $p_{\min}$  calculated with the 1000 replicated NRSP p-values.

# A Upper-bound for Replicated NRSP-based Test p-values

- Suppose  $p_1, \dots, p_J$  are  $J$  replicated NRSP test p-values for a fitted model.
- A formula for bounding tail probabilities of order statistics of correlated samples gives the following inequality for the  $r$ th order statistics  $p_{(r)}$ :

$$P(p_{(r)} < t) \leq \min \left( 1, t \frac{J}{r} \right). \quad (4)$$

- Based on (4), a p-value upper bound for observed (simulated)  $r$ th statistics  $p_{(r)}^{\text{obs}}$  is given by  $\min \left( 1, p_{(r)}^{\text{obs}} \frac{J}{r} \right)$ .
- To avoid the selection of  $r$ , we report the minimal upper bound for  $r = 1, \dots, J$ , denoted by  $p_{\min}$ :

$$p_{\min} = \min_{r=1, \dots, J} \min \left( 1, p_{(r)}^{\text{obs}} \frac{J}{r} \right). \quad (5)$$

When a model has a small  $p_{\min}$ , it is highly suspected that the model can be improved for better fitting the dataset.

# Results of Statistical Tests

**Table 2:** Model diagnostic test p-values or  $p_{\min}$  for NRSP tests and AIC values of different models for the breast cancer data. The numbers in brackets for NRSP tests are the percentages of replicated NRSP test p-values being  $\leq 0.05$ .

Model	Weibull	log-logistic	log-normal	log-normal with log(nodes)
AIC	5181	5153	5139	5121
NUSP-CSF p-values	< 0.0001	< 0.01	0.133	0.172
NRSP-SW $p_{\min}$	< 0.0001 (100.00)	< 0.01 (99.00)	0.436 ( 6.90)	0.529 (5.70)
NRSP-SF $p_{\min}$	< 0.0001 (100.00)	0.015 (97.00)	0.485 ( 5.80)	0.637 (3.50)
NRSP-AOV $p_{\min}$	0.020 ( 60.40)	0.007 (46.00)	<b>0.052 (52.40)</b>	0.999 (0.50)

# Checking Non-Linearity

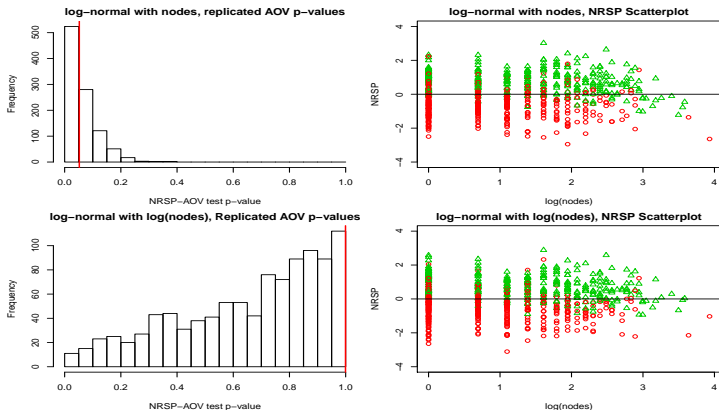

Figure 4: NRSP non-linearity residual diagnosis for the breast cancer data. The red vertical lines in the histograms of replicated NRSP-AOV p-values show the  $p_{\min}$  values.

# Conclusion

- This paper has proposed using randomized survival probabilities (RSPs) to conduct model diagnostics for censored regression. NRSP residuals are approximately distributed with  $N(0, 1)$  under the true model. With this unified reference distribution for NRSP residuals, we can conduct a wide variety of residual diagnostics for censored regression.
- Our simulation studies show that a non-linearity test with NRSP residuals has significantly higher power in detecting non-linearity than existing GOF tests. The real data analysis shows that the NRSP residual diagnostics successfully captures a subtle non-linear relationship in the dataset.
- R functions for computing NRSP residuals for `survreg` and `coxph` objects are also available on my website:  
<https://longhaisk.github.io/>

- We are working on extending the NRSP residual diagnostics to shared frailty models (survival models with random effects).
- We expect that many other specific model mis-specification tests that target a particular model discrepancy have higher powers than GOF tests. For example, statistical tests for checking proportional hazard assumption in Cox regression seem to be demanded very often. We are working on developing such specific tests based on NRSP residuals.
- Cross-validatory NRSP residual (Z-residual). We are working on developing software packages for computing cross-validatory Z-residuals for shared frailty models and investigating the effect of using cross-validation or not.
